SINTEF – Brazil Cooperation in Aquaculture Research

- Project funded by the Norwegian Research Council (2014 2017)
- Main topic: Potential for (marine) aquaculture in Brazil
 - Marine juvenile production technology
 - Marine Algea
 - Markets and techno-economic performance
 - Private /public capacities for developing marine aquaculture
- Cooperation to four peer universities and institutions in Brazil
- Scientific and user advisory group:
- Eric Routledge, EMBRAPA, Brazil
- Alberto Nunes, The Institute of Marine Sciences, LABOMAR, Brazil
- Trina Galloway, SINTEF do Brasil

Marine Aquaculture in Norway - Topics

- <u>Status</u> : Growth and good markets
 - From small scale to industrial production
 - Still commodity supplier
- <u>Challenges</u>: Sustainability Easy to say – difficult to apply! Who pays ?
- <u>Trends</u>: Technology shift about to come but, costly search for alternatives
 - Landbased ? Open Ocean? Closed floating devices ? Intensive R&D
- <u>Future</u>: Global need for fish as food

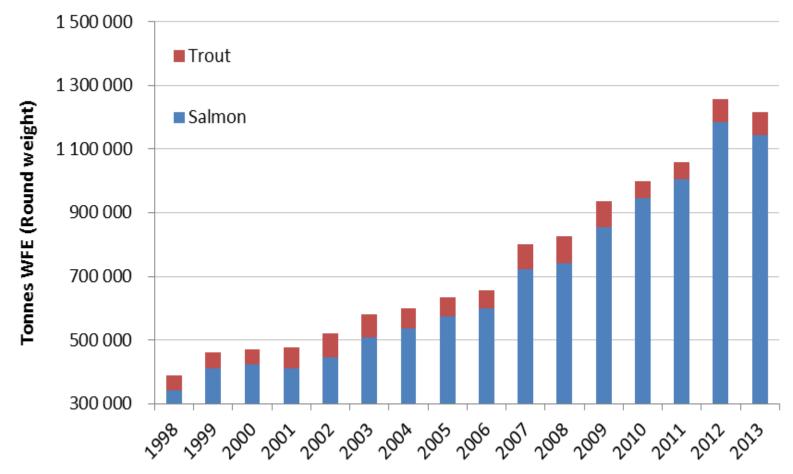

Norwegian Aquaculture Output 1998 - 2013

Sustainable farming – Need for new Production Models

- Lessons Learned
 - Environmental zone management
 - Farm fallow periods
 - Biosecurity along the entire value chain
- New technology
 - Open Ocean Farming
 - New (stronger) net pens
 - "Double Net Pens / Closed floating Containments (regulated water intake)
 - Semi land-based production cycles
 - Land-based production
- Extensive Research and Development needed for finding solutions to environmental issues. (Industry finance 50 % of total aquaculture research in Norway ; 400 Mill NOK

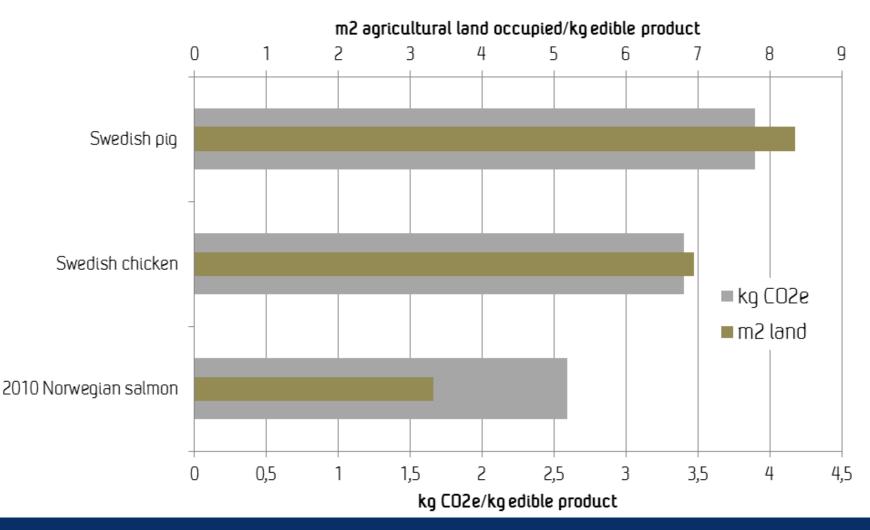

Seafood in perspective – Carbon footprints (Norway)

(kg CO₂e/kg edible part at slaughter/landing)

Carbon footprint – use of land

The 'extreme' development trend in cage size in salmon farming

ONE large cage would hold 1 000 tons of fish (in SEtAsiaqstilleonly 100m circumference and 100 tons)

Volume increased 100 times compared to pioneer days in Norway:

40m circumference cage with 4 m deep net = 550 m^3

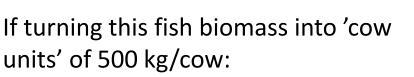

157m circumference cage with 30 m deep net = 60 000 m³

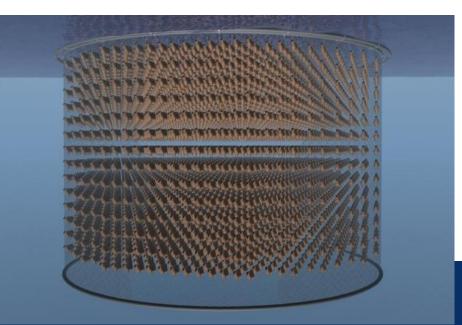

1 000 tons of fish biomass in one cage

That's why!!! it takes a skilled 'shepherd' plus 'something more' to tend one cage

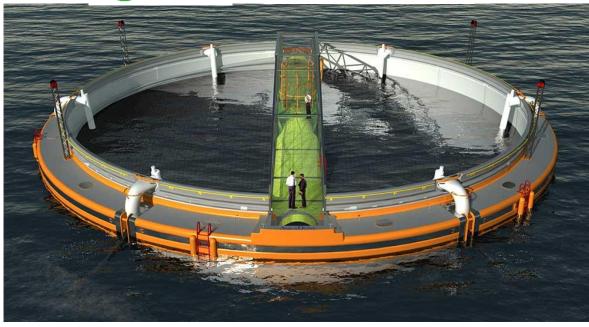

It equals taking care of 2 000 cows; but the challenge is in addition to the large number that you cannot see them!

New technology: Closed floating containments

Floating fish farm

- Reduce risk of escapes
- Prevent sea lice by pumping water from deeper layers

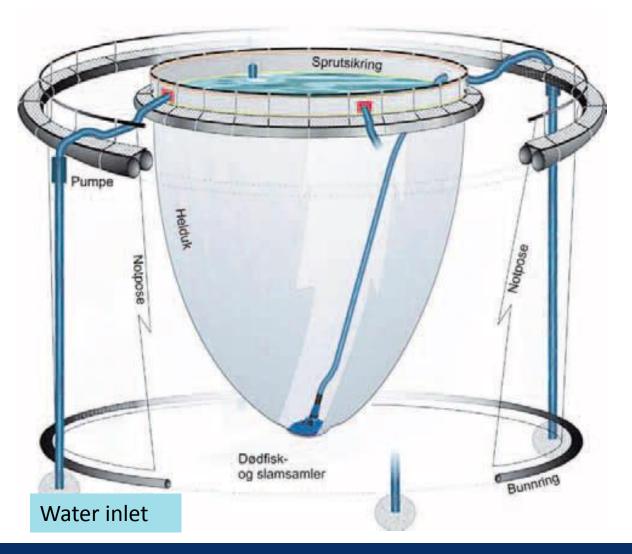

AquaDome[®] is built of composite plastic, GRP, which is a very sturdy material. It has strong operational, technical and labor-saving solutions made possible by the patented shape.

AquaDome[®] is designed as a hemisphere. The size is 27.7 meters in diameter, 15 m deep with an internal volume of 5560 m³. Sufficient buoyancy is provided by the cavity in the combined float collar and walkway.

The design and choice of materials helps the AquaDome[®] withstand strong forces acting on it, in the form of currents, waves and icing. The hemisphere shape makes it possible to equip the device with a semicircular arm of rigid material, which simplifies operations associated with the cleaning of the inside wall, and fish handling.

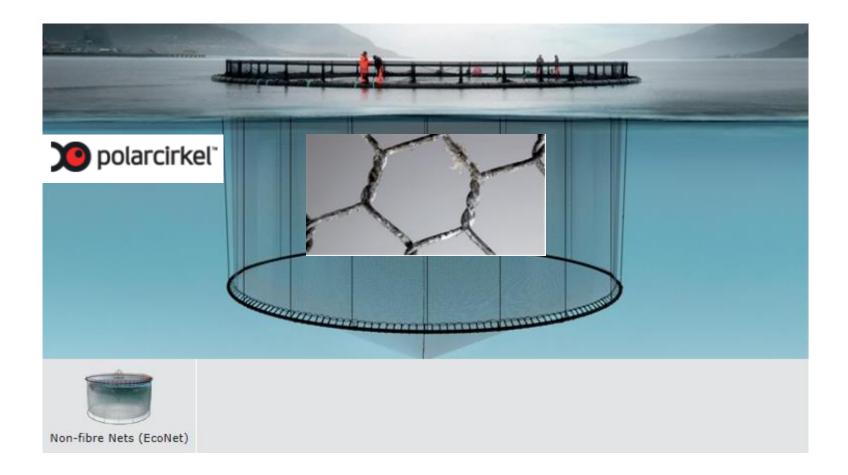

Closed nets

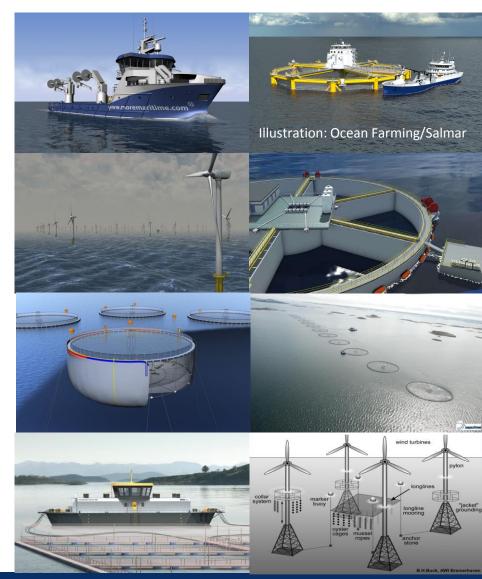

None-fibre Nets (ECONet)

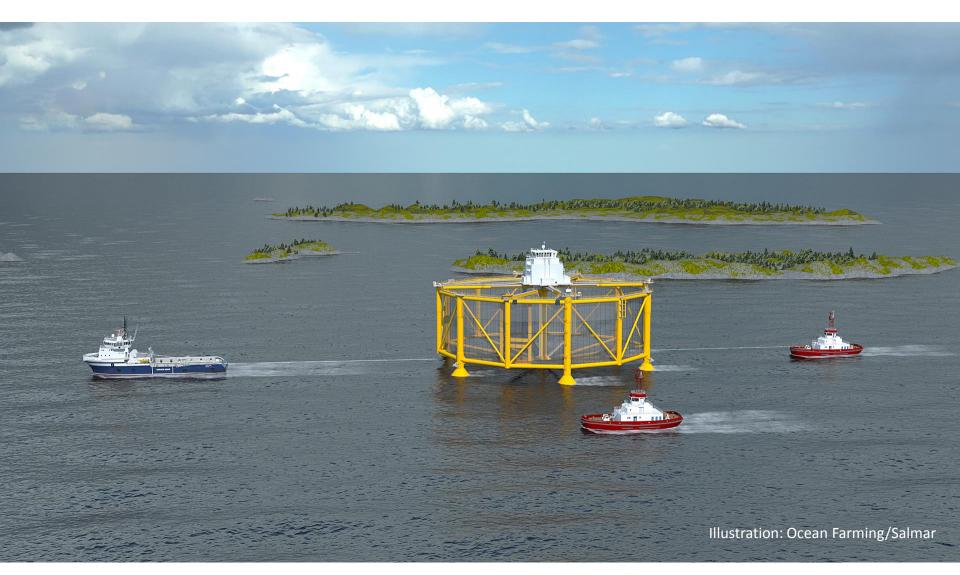

Blue –blue sector collaboration to increase innovation

- Transfer of knowledge , competence and solutions
 - Operations in the wave zone
 - Offshore wind
- Synergies in collaboration
 - Reliability and operability
 - Risk management and design
- Challenges and constrain
 - Operational limits for feeding
 - Operational limits for handling, delousing and changing nets
 - Transfer of fish
 - Biological limits
- Existing, closed containment or offshore
 - Need several kind of solutions

Ocean Fish Farming

Ocean Fish Farming

Foto/illustrasjonsrettigheter må angis ved bruk SINTEF Fisheries and Aquaculture

Ocean Fish Farming

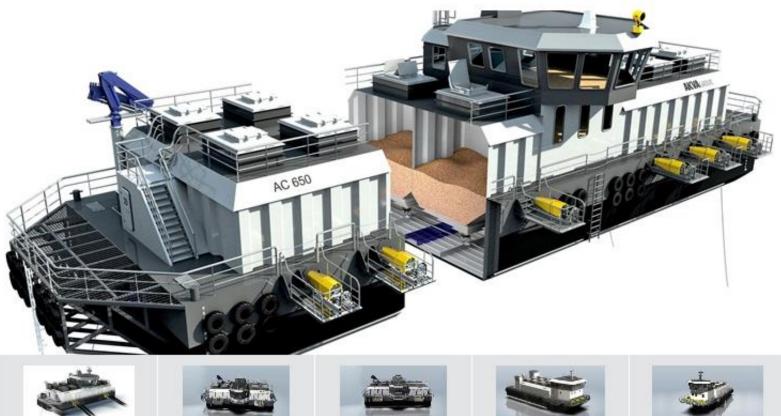

Diameter 110 m, operating draft 42 m an a total height 67 m. The production volume is 8 times the volume of a standard fish farm.

Standard Feed Barges

Feed Barges

AC 450 Panorama

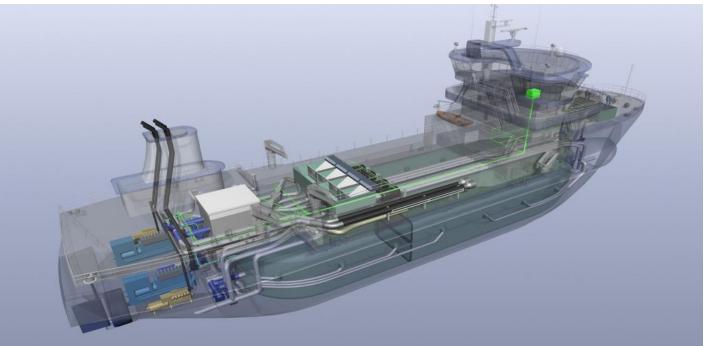

AM 320 Comfort

Next generation Well-boat Technology

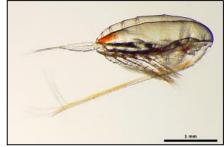

- Biosecurity, efficiency, fish welfare, gentle fish handling and the environment
- Closed water systems cleaning and disposal
- Pharmaceutical treatments
- Improvement of the interaction with fish farms
- DP (dynamic positioning) systems and other navigational aid

Need for Feed -> Harvesting zooplankton?

- The *Calanus finmarchicus* is available in huge amounts in the North-East Atlantic
- Annual biomass Norwegian waters approx 120 Million tonnes
- Compared to cod: ~40 times more Calanus
- High value ingredients for both
 - Feed industry
 - Pharmaceutical industry
- Norwegian fishing fleet is extremely innovative

Calanus finmarchicus (Photo: Dag Altin, BioTrix)

Calanus catches in trial fishery (Photo: Snorre Angell, Calanus AS).

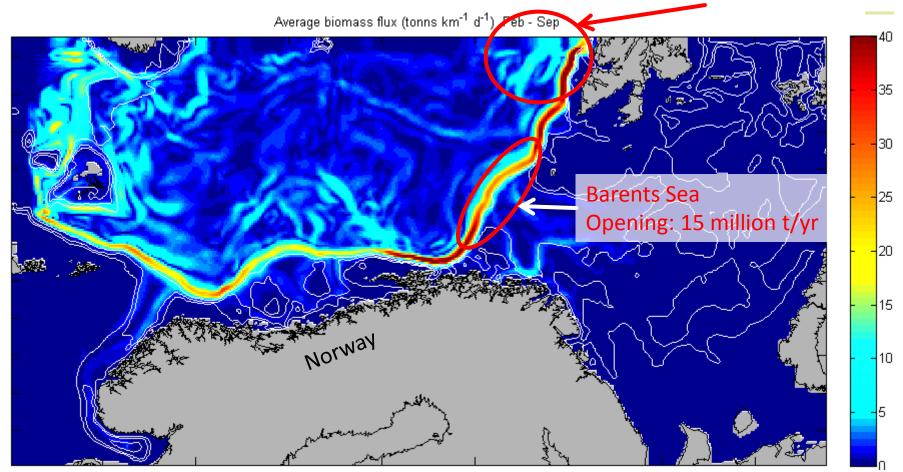

Calanus trawl. (Photo: SINTEF)

Average calanus biomass transport (Feb-Sept)

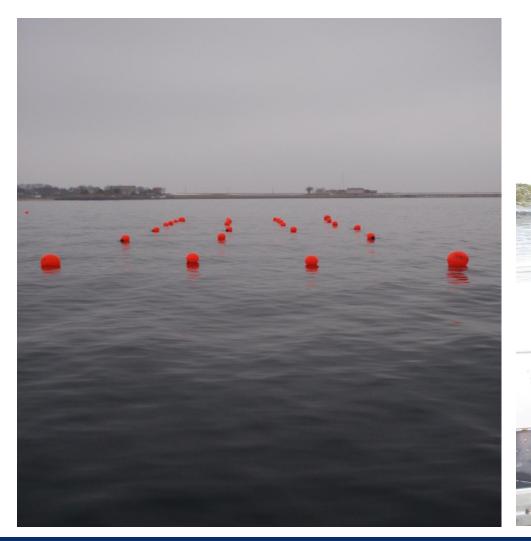

Fram strait: 30 million t/yr

Source: Norwegian Directorate of Fisheries, seafood.no, DKNVS/NTVA (2012): "Value created from productive oceans in 2050"

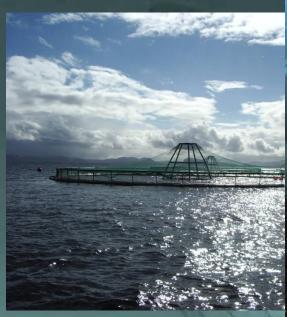

Another growth opportunity: Seaweed cultivation

Integrated Multi-Trophic Aquaculture

Intensive fed aquaculture (salmon)

Filtering species culture (mussels) "Photosynthetic aquaculture" (seaweed)

Future potential of growth

- Global need for food ; Wild catch of fish supply cannot increase !
- Aquaculture needs to produce around 4 % more marine proteins each year to satisfy demand up to year 2020 (FAO forecast)
- Only 2 % of food production comes from the ocean
 - Salmon farming saw a strong global harvest growth between 1996 and 2005, with a CAGR *) of 9,6 %, but "biological carrying capacity diminish growth".
 A.H Aarskog, CEO, Marine Harvest

Future growth in salmon farming expected to CAGR of 2,9 % between 2014 -2020

- Norwegian Fish Farmers Association goal; 2,7 million tons by 2025
- *) CAGR = Compound Annual Growth Rate
